## Appendix A.1: Logic Model for the Process and Impact Evaluation of MRC

## Appendix A.2: Illustration of the Randomization Process

## Appendix A.3: Findings from Sensitivity Analysis

The sensitivity analysis was performed by first classifying each student in the original sample as either included (coded as 1) or excluded (coded as 0) from the final analysis. Students were excluded from the analysis due to withdrawal from a sampled school or due to a significant amount of missing data resulting from chronic school absence. A logistic regression was then performed predicting the likelihood of inclusion in the final analysis. The analysis indicates that Black, Hispanic, and Other Race students were less likely to be included in the final analysis sample. Also, students assigned to the program group were less likely to be included in the final analysis than students in the control group. Although some demographic characteristics were more likely to be associated with the excluded students, these results should be viewed in the context of the baseline analysis (presented in Table III.4. of the final report), which show that the baseline student demographics used in the final analysis were generally equivalent across program and control groups.

## Appendix A.5: Detailed Methodology

As explained in section III.B of the report, three sets of analyses were conducted to answer the study's research questions:

1. What is the impact of the MRC program on student literacy outcomes?
  - a. Does the impact vary by student characteristics/demographics?
  - b. Do assessment scores vary by AmeriCorps member characteristics/demographics?
2. Does the impact of the program vary week to week? Does the number of weeks of intervention (i.e., dosage) impact student literacy outcomes?
3. Does participation in MRC have a longer-term impact on student literacy outcomes as measured at the end of the school year?

The first set of analyses focus on the Fall-Winter Experimental Study data collected during the first semester of the 2012-2013 school year and was used to answer the first research question (RQ1), which assesses the impact of the MRC program on student literacy outcomes. The Fall-Winter experimental analyses employed growth models utilizing weekly progress monitoring data as primary outcomes and the Fall benchmarks as covariates to assess the impact of the MRC program on student literacy proficiency at each grade level.

Because it was not possible to continue the experimental RCT throughout the entire school year, all students who were eligible at the Winter benchmark to participate in the MRC program were allowed to receive services during the second semester of the 2012-2013 school year. Data from the first and second semester were combined to answer the second and third research questions aimed at assessing the week to week impact of the program on student literacy outcomes (RQ2), as well as the longer-term impact of the program on student literacy outcomes (RQ3).

### Analysis 1: Fall-Winter Experimental Analyses

---

#### Impact Analysis

The overall goal of the Fall-Winter Experimental Study was to obtain a measure of an average treatment effect of the MRC program by grade. In a simple experiment, this measure of impact would be a straightforward comparison of program (treatment) and control group means at the end of the experimental period. However, because the evaluation team was able to obtain weekly assessment data on all students in the study, we were able to estimate the impact of the program on participants as a varying quantity over the weeks of the experimental period (Fall-Winter). This approach required that we estimate the effect of the MRC program on a weekly basis concurrent with typical growth trajectories. Therefore, our experimental analysis consisted of two phases for each grade. In the first

phase, a statistical model was developed to produce a set of regression coefficients that summarized the observed data. In the second phase, we then used the estimated model to predict marginal (average) scores for program participants and control group students at several weekly points. From these points, the evaluation team estimated the difference between program and control group students to measure program impacts. We then calculated the precision of our estimates for statistical tests.

The modeling of the MRC data presented several challenges. First, as weekly assessments were measured during a non-linear developmental period, treatment effects had to be measured as offsets to typical growth patterns. This was accomplished by employing a difference-in-difference technique, whereby program participation moderated the estimated growth trajectory of students. Since growth tends to be non-linear during early childhood years, growth trajectories in kindergarten were also smoothed using quadratic time variables.

Second, the distribution of the assessment metrics, especially in Kindergarten, tended to be highly skewed across the weeks of data, and so statistical models that assumed normality required log-transformed outcomes. Thus, we transformed all outcomes and benchmarks by taking the log of the score plus 1 (i.e.,  $y^* = \ln(y+1)$ ). Once the model was estimated, predicted scores, "xb," were transformed back into the original metric with  $\exp(xb)-1$ .

Third, the analysis was further complicated by the nested nature of the data. Each observation is a weekly assessment nested within a student, who is in turn nested within a pair, which in turn is nested within a school. Thus, typical regression techniques would produce standard errors that may lead to false statements about effects. We instead employed mixed models or Hierarchical Linear Modeling (HLM) that estimated several random effects to produce the appropriate standard errors. Finally, since these data were weekly measurements, there was likely to be temporal autocorrelation across each student's residuals. In other words, the score at week 2 was likely to be highly correlated with the score at week 1. Thus, our models employed autoregressive residuals to adjust the standard errors for this temporal correlation.

Our final mixed models encompass all these features. In the model for each grade, the assessment from week  $w$  of student  $i$  in pair  $j$  in school  $k$  is a function of a set of effects for the trajectory,  $\sum_{q=1}^l \pi_{qijk} w^q$ , with autoregressive residuals. The intercept is then a function of the benchmark scores,  $b$ , an indicator of alternative treatments,  $a$ , and program participation,  $p$ . The intercept equation also includes random effects for the student,  $e$ , pair,  $u$ , and school,  $v$ . Finally, each of the  $q$  trajectory polynomials is modeled as a function of program participation,  $\beta_{q0} + \beta_{q1} p_{ijk}$ . Note that the outcome and benchmarks are transformed into a logged metric.

Thus, our final mixed model was

$$\ln[y_{wijk} + 1] = \pi_{0ijk} + \sum_{q=1}^l \pi_{qijk} w^q + \rho r_{wijk}$$

where

$$\pi_{0ijk} = \beta_{00jk} + \beta_{01jk} \ln[b_{jk} + 1] + \beta_{02jk} a_{ijk} + \beta_{03jk} p_{ijk} + e_{ijk} + u_{jk} + v_k$$

and

$$\pi_{qijk} = \beta_{q0} + \beta_{q1} p_{ijk}$$

We then estimated this model for each grade. Note that for grades 1, 2, and 3 that  $l = 1$ , but for kindergarten  $l = 2$ . To maintain generalizability, we employed school-level sampling weights in our estimation. The key parameters in these models are represented as  $\beta_{q1}$ , which is the difference-in-difference effect. The estimated models are presented in Appendix B.1.

The second phase of the impact analysis was to predict scores for program and control groups by week, and test the weekly differences statistically. Specifically, we estimated the outcomes (in the original score metric) for program and control students assuming average benchmarks and no alternative treatments

$$\hat{y}_w = \begin{cases} \exp\left[\beta_{00} + \beta_{01} \overline{\ln[b+1]} + \sum_{q=1}^l (\beta_{q0}) w^q\right] - 1 & \text{for control students} \\ \exp\left[\beta_{00} + \beta_{01} \overline{\ln[b+1]} + \beta_{03} + \sum_{q=1}^l (\beta_{q0} + \beta_{q1}) w^q\right] - 1 & \text{for program participants} \end{cases}$$

What is revealing in the above expression is that the only differences between the control and program predictions are the terms  $\beta_{03}$  (which is the initial difference between program and control students) and  $\beta_{q1}$  (the difference-in-difference effects). Each point estimate had an estimated variance (i.e., sampling error) that was used to test whether the difference was 0. The variance of the estimates employed information about the model variance, so the statistical tests contrasting control and program estimates employed information about the precision of the model.

Two types of subgroup analysis were employed by the evaluation team. First, performed an omnibus Chi-square test of the  $\gamma$  effects (the subgroup effects on the difference-in-difference coefficients) to determine whether subgroup membership impacted the program effects on student trajectory. If an impact was determined, the evaluation team employed the second phase of the subgroup analyses, in which we again produced predicted values and tested the

differences between program and control students. For these analyses, we included a set of subgroup indicators,  $S$ , that moderated the trajectory effects and the impact of program participation on the trajectory effects,

$$P_{ijk} \sum_s \gamma_{qijk} S_{ijk} .$$

$$\ln[y_{wijk} + 1] = \pi_{0ijk} + \sum_{q=1}^l \pi_{qijk} w^q + \rho r_{wijk}$$

where

$$\pi_{0ijk} = \beta_{00jk} + \beta_{01jk} \ln[b_{ijk} + 1] + \beta_{02jk} a_{ijk} + \beta_{03jk} P_{ijk} + \sum_s \beta_{0sjk} S_{ijk} + e_{ijk} + u_{jk} + v_k$$

and

$$\pi_{qijk} = \beta_{q0} + \beta_{q1} P_{ijk} + \sum_s \beta_{qsjk} S_{ijk} + P_{ijk} \sum_s \gamma_{qsjk} S_{ijk}$$

### Member- and School-Level Random Effects on Impacts

In order to determine whether members or schools were influential on gains for those assigned treatment, a intraclass correlation (ICC or  $\rho$ ) analysis was conducted. Intraclass correlations measure the portion of the total variation in an outcome that is associated with various levels of analysis. In this case, the member ICC,  $\rho_{member}$ , measure the degree to which different students assigned the same member correlate on changes or gains in their assessment scores within a school. The school-level ICC,  $\rho_{school}$ , measures the degree to which students, who are located within the same school, but assigned to different members, correlate with one another.

We estimate these parameters using a mixed model where the difference between the winter and fall benchmark score for the  $i$ th child assigned member  $j$  in school  $k$  is a function of an overall mean difference,  $\alpha$ , a member random effect,  $\phi_{jk}$ , a school random effect,  $\zeta_k$ , and a within-member student random effect,  $\epsilon_{ijk}$ .

$$y_{ijk}^{(2)} - y_{ijk}^{(1)} = \alpha + \phi_{jk} + \zeta_k + \epsilon_{ijk}$$

We then estimate the variances components  $\sigma_{member}^2 = var(\phi_{jk})$ ,  $\sigma_{school}^2 = var(\zeta_k)$ , and  $\sigma_{student}^2 = var(\epsilon_{ijk})$ , and calculate two ICCs

The ICC for members is

$$\rho_{member} = \frac{\sigma_{member}^2}{\sigma_{member}^2 + \sigma_{school}^2 + \sigma_{student}^2}$$

and for the school it is

$$\rho_{school} = \frac{\sigma_{school}^2}{\sigma_{member}^2 + \sigma_{school}^2 + \sigma_{student}^2}.$$

A key component in evaluating ICCs is to measure the uncertainty associated with them. Recent work by Hedges, et al (2012) has provided a formula for the estimate of the variance of ICCs based on the estimated precision of the derived variance components.<sup>1</sup>

### AmeriCorps Member Fixed Effects on Assessment Scores

To assess the impact of member fixed characteristics (i.e. observed demographics) on treatment students' assessment scores, the evaluation team estimated another statistical model on a set of data where the assessments were standardized within grade and combined into a single model. In other words, we estimated standardized assessment scores within each grade, combined the data, and fit a model predicting scores with member characteristics (age, education years, specialized degree, full time status, tenure status, race/ethnicity, and gender), a simple time trend, student gender, and the interaction between member and student gender. Since the outcomes are standardized, the effect is estimated from the change in standard deviations. Note that while we fit a multilevel model, the variance components for members are confounded with the variance attributed to grades and schools because members were assigned specific grades and schools. This required an additional set of models to test whether member random effects were substantial enough that they should be included in the final model. To answer whether members had unique random effects on student outcomes, we fit grade-specific unconditional models (i.e., no controls) and calculated the correlation of outcomes from students tutored by the same member. We found little variance attributed to random member effects and, since the resulting ICCs were small, member effects were not accounted for in the final model.

### Analysis 2: Full Year Non-Experimental Analysis

For the second set of analyses, data from the first and second semester were combined to answer the second research question, which focused on better understanding patterns of week over week growth in reading proficiency by grade. After the first semester, all students who were eligible at the Winter benchmark to participate in the MRC program were allowed to receive services (program and control group members). Therefore, while the evaluation team employed similar analytic coding strategies and estimation techniques as applied in the first analysis, the second analysis differed in that we acknowledged that variation in dosage existed over the course of the year.

---

<sup>1</sup> Hedges, Larry V., Hedberg, E. C., and Kuyper, Arend M. 2012. *The Variance of Intraclass Correlations in Three- and Four-Level Models*. Educational and Psychological Measurement.

Therefore, our primary predictor was not program participation as a moderator of trajectory, but instead the number of cumulative weeks of receiving the program.

The cumulative number of weeks of receiving the program was coded in such a way that for any given week, the value was the number of sessions each student received up to and including that week. For example, if a student never received sessions, their weekly value was always 0. If a student received sessions each week for the whole year, they were coded as 1 for the first week, 2 for the second week, etc. Also, when a student stopped receiving sessions, the final weeks of the year were coded the same as their final week of sessions. For example, if a student stopped receiving sessions at week 5, they were coded as 5 for the remaining weeks. This allowed individual student variation in the pattern of sessions, while fitting a model that estimated the effect of receiving an additional week of sessions.

Similar to our Fall-Winter experimental analysis, we again fit a multilevel model; however, we removed the random effect for pairs since other pair members were allowed the program after the first semester. In this model, we coded each week with the dichotomous variable for receiving the program,  $r$ , and used the cumulative sum of this variable as a predictor. As with our Fall-Winter experimental analysis, we again use polynomials to capture non-linearity in kindergarten. We also controlled for the semester,  $d$ , and original program assignment,  $p$ . The final statistical model is

$$\ln(y_{wik} + 1) = \pi_{0ik} + \pi_{1ik}d_w + \sum_{q=1}^l \zeta_{qik}w^q + \sum_{c=1}^l \kappa_{cik} \left( \sum_{g=1}^w t_{wik} \right)^c + \rho r_{wik}$$

where

$$pi_{0ik} = \beta_{00k} + \beta_{01k}p_{ik} + e_{ik} + v_k$$

where  $\sum_{g=1}^w t_{wik}$  is the number of cumulative sessions for that week.

To summarize the results of this model, we estimated the tangential change in the outcome

$$\frac{\partial y_{wik}}{\partial \sum_{g=1}^w t_{wik}}$$

when moving from 0 to 1 weeks of sessions, 1 to 2 weeks of sessions, and so on. We caution that these effects are not necessarily causal, since receiving treatment is a function of performance on benchmark. To explain, if a student exceeds benchmarks in the Fall they qualify to exit the MRC program and stop receiving treatment. If, however, their performance is relatively close, but still below benchmark in the Winter they could re-enter the program. Thus,

negative associations between the number of sessions and student outcomes are likely due to assigning the program to struggling students rather than the program having causally detrimental effects.

### Analysis 3: Exploratory Analysis

---

#### Analysis of Probabilities of Group Membership

The ultimate goal of the program is to matriculate students into an "above benchmark" status. Therefore, our final analysis examines this question by asking which trajectory pattern are program participants most likely to follow. We conceived of two plausible methods to measure this. First, we consider nominal categories of trajectory patterns and estimate the likelihood of a student falling into one of these nominal categories based on the experimental assignment. Our second approach views trajectory as a more linear concept that is altered during and after exposure to the program.

In the first approach, we coded each student as belonging to the following categories:

- No program effect (always below benchmark)
- Temporary program effect (moving above and below benchmark and ending the school year below)
- Final program effect (starting below benchmark, then eventually progressing and remaining above benchmark for the remainder of the school year)
- Always above benchmark
- Negative effect (above, then ending below benchmark)

Of these five patterns, the latter two represented a very small portion of students (4) and were not included in the final analysis. We performed a multinomial logistic regression analysis predicting the likelihood of students falling into each of the three major classes or groups as a function of program assignment, cumulative sessions, and demographics. We also included an interaction term between program assignment and cumulative sessions, again because some students that were initially assigned to the control group received sessions in the second semester.

Once we estimated the model (provided in Appendix D), the evaluation team then predicted the likelihood of following each group pattern for two average students who received the same dosage of the program, specifically 10 tutoring sessions, with the only difference being that one student was originally assigned to the program group and the other to the control group. The key comparison is the likelihood of falling into the "final program effect" category for those students assigned to the program group versus the control group. Because all other differences between the two theoretical students were held constant in the model, including program dosage (i.e., 10 sessions of tutoring), the only difference is the timing in which the students would have received MRC tutoring (i.e., first vs. second semester).

Therefore, the findings from this analysis indicate whether early intervention of the program results in a higher or lower likelihood of falling into the “final program effect” group.

### Spline Analysis

Spline models are typical in analyses that seek to fit a model to data measured over time, where specific events are hypothesized to change the trajectory. In our case, the spline models measure not only the growth of students over the course of the year, but specifically how those growth patterns are altered by participation in the program. The spline model allows for a linear trajectory across the entire school year, and also allows for this trajectory to be adjusted based on two phases: during treatment,  $D_1$ , and after treatment,  $D_2$ . Thus, the spline model we fit to the data is

$$y_{it} = \beta_0 + \beta_1 Week_{it} + \sum_j (D_{j, it} \times Week_{it}) + e_{it}$$

The purpose of the analysis was to examine changes to the trajectory of student achievement prior to, during, and after receiving MRC tutoring, regardless of initial assignment to conditions (program or control group). We fit the model on a subset of cases in each grade that received at least one weekly session of tutoring during the school year. We also limited the analysis to only 10 weekly tutoring sessions to remove the cross-semester (i.e., first vs. second semester) effects of low performing students who would have required a larger dosage of the MRC intervention.

## Appendix B.2: Findings from Robustness Analysis

The evaluation team also tested the variability of the program effect at the assigned pair level. To do this, we estimated a simpler model with a linear trajectory and a random effect for the impact of program participation on trajectory,  $z$ .

$$\ln[y_{wijk} + 1] = \pi_{0ijk} + \pi_{1ijk}w + \rho r_{wijk}$$

where

$$\pi_{0ijk} = \beta_{00jk} + \beta_{01jk} \ln[b_{ijk} + 1] + \beta_{02jk} a_{ijk} + \beta_{03jk} p_{ijk} + e_{ijk} + u_{jk} + v_k$$

and

$$\pi_{1ijk} = \beta_{10} + \beta_{11jk} p_{ijk}$$

and

$$\beta_{11jk} = \lambda_{110} + z_{jk}$$

where,  $\lambda_{110}$  is the average of the pair-specific differences in the trajectory based on program participation and  $z$  is the difference between the pair-specific difference in the trajectory and the average.

After the model was estimated, we then predicted the random effect. This allowed us to estimate a pair-specific effect. We then estimated the mean and confidence interval of this effect. If the confidence interval did not include 0, we found support for program effects. We also calculated the proportion of effects that were positive as a measure of robustness.

Table B.2.1 showcases the results of this analysis. As expected, we found average positive effects on all simple trajectories (noted as average pair difference from model in the table). We also found non-zero variance of this effect at the pair level for all grades except third (noted as variance of difference in the table).

When we computed the pair specific effect from the model, we found the mean pair effects were consistent with the model estimated mean effect. These means were, on average, statistically different than zero.

Finally, looking at the proportion of pairs with an estimated positive effect, we find that 92 percent of kindergartener pairs, 97 percent of first graders, 79 percent of second graders, and 70 percent of third graders, showed a positive effect on a simple trajectory.

## Appendix C: IES What Works Clearinghouse Analysis

The What Works Clearinghouse (WWC), an initiative of the Institute of Education Sciences at the U.S. Department of Education, is the leading resource in the field of education that independently identifies and evaluates scientific evidence of effectiveness of educational practices, programs and policies.<sup>2</sup> Given the size of the MRC program within the state of Minnesota and the growing interest in replicating the MRC model in other states, we anticipate WWC interest in reviewing the results of the MRC K-3 impact evaluation. As such, we present here an analysis of the MRC K-3 impact evaluation data that adheres to WWC review criteria.

For the WWC analysis, the evaluation team conducted four separate grade-specific regression analyses comparing program and control group students' literacy outcomes as measured by their Winter benchmark scores. In addition, using Analysis of Covariance (ANCOVA) models, we tested the effect of treatment on Winter benchmark scores that included the Fall benchmark score as a covariate. The results of the WWC analysis confirm the statistically significant and positive impact of the MRC program on Kindergarten and first grade students' literacy skills. No statistically significant impact was found for second and third grade students. Below, we outline details of the WWC analysis.

### Outcomes

---

As described in Section II.D, the evaluation used outcome data collected by the MRC program using the AIMSweb assessment system.<sup>3</sup> Three specific literacy skills that are appropriate for particular grade levels were assessed using AIMSweb: 1) letter sound fluency (Kindergarten), 2) nonsense word fluency (first grade), and 3) oral reading fluency (i.e., R-CBM; second and third grades). The AIMSweb assessments, published by Pearson, have been shown to have good measurement properties in terms of retest reliability for R-CBM,  $>.90$  and letter sound fluency  $>.82$ ; and alternate form reliability for nonsense word fluency  $>.74$ .<sup>4</sup> Depending on the criterion referenced test and time of administration, criterion validity ranged from .58 to .72 for letter sound fluency in kindergarten, .43 to .72 for nonsense word fluency in first grade, and .60 to .81 for R-CBM in 2<sup>nd</sup> and 3<sup>rd</sup> grade.<sup>5</sup> Since the outcome metrics varied by grade level, our analysis is presented as a separate study for each grade.

<sup>3</sup> <http://www.aimsweb.com/>

<sup>4</sup> <http://www.aimsweb.com/resources/research-articles-and-information>

<sup>5</sup> See the *AIMSweb Technical Manual* (2012) for a detailed report on each outcome measure's reliability and validity.

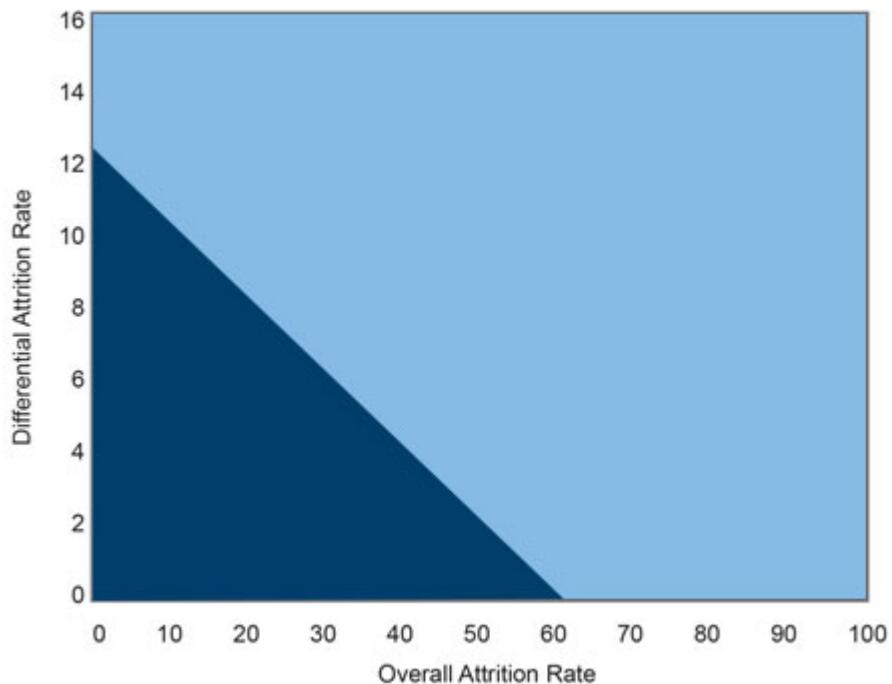

## Randomization

The evaluation implemented a randomized controlled trial, experimental design where randomization to the program and control conditions occurred at the level of the student. Because students were randomized, it is not necessary to demonstrate equivalence between the program and control groups *a priori*. Likewise, student level randomization eliminates the need to consider the effects of school clustering on uncertainty.

## Attrition

For each grade K-3, we demonstrate low levels of attrition assuming the “liberal” standards outlined in the *WWC Evidence Review Protocol for Early Childhood interventions (Version 2)*.<sup>6</sup> The liberal standards are appropriate because in early childhood interventions the mechanism of attrition is unlikely due to program assignment. Any combination of overall attrition and differential attrition in the lower, left corner (dark gray zone) of Figure C.1 below is considered low attrition.

**Figure C.1: Acceptable Levels of Overall Attrition by Differential Attrition**

In total, the evaluation team randomized 1,530 students to either the program or control conditions based on fall assessment scores.<sup>7</sup> Table C.1 below shows the number of students in each condition by grade.

<sup>6</sup> [http://ies.ed.gov/ncee/wwc/pdf/reference\\_resources/ece\\_protocol\\_v2.0.pdf](http://ies.ed.gov/ncee/wwc/pdf/reference_resources/ece_protocol_v2.0.pdf)

<sup>7</sup> See section III.D for a detailed description of the randomization process

Table C.1. Number of Students Assigned to and Retained in Each Condition by Grade

Grade	Assigned Program (Retained/Analytic N)	Assigned Control (Retained/Analytic N)	Total (Retained/Analytic N)
Kindergarten	207 (144)	194 (150)	401 (294)
First Grade	228 (197)	222 (183)	450 (380)
Second Grade	170 (140)	148 (114)	318 (254)
Third Grade	196 (169)	165 (142)	361 (311)
Total	801 (650)	729 (589)	1,530 (1,239)

A number of students (291) were not available for Winter benchmark testing. This attrition poses a risk to the experimental results if the overall rate is too high or the difference in the rate between program and control groups is too large. Overall attrition was calculated as:

$$Overall = X = \frac{\text{Randomized Sample}}{\text{Analytic Sample}} \times 100$$

The differential attrition is the absolute value of the difference in the attrition rates between those assigned to the program group and those assigned to the control group. Differential attrition was calculated as:

$$Differential = Y = \left| \frac{\text{Randomized Sample (Program)}}{\text{Analytic Sample (Program)}} - \frac{\text{Randomized Sample (Control)}}{\text{Analytic Sample (Control)}} \right| \times 100$$

Table C.2 below lists the overall attrition rate (the X axis in Figure C.1 above) and the differential attrition rate (the Y axis in Figure C.1 above) by grade.

Table C.2. Overall and Differential Attrition Rates by Grade

Grade	Overall Attrition (X Axis)	Attrition for Program Group ( $A_p$ )	Attrition for Control Group ( $A_c$ )	Differential Attrition (Absolute Value; Y Axis)
Kindergarten	27	30	23	7
First Grade	16	14	18	4
Second Grade	20	18	23	5
Third Grade	14	14	14	0
Total	19	19	19	0

When plotting the combination of overall and differential attrition on the WWC attrition guide, illustrated in Figure C.1 above, we find acceptably low attrition levels for each grade (i.e., levels of overall attrition by differential attrition rates are in the green area of the figure).

## Effect

---

Table C.3 below presents the results in effect-size units (Hedges'  $g$ ) and the original assessment metric of four separate grade specific analyses comparing program and control group students' literacy outcomes measure by their Winter benchmark scores. The table also provides the results of Analysis of Covariance (ANCOVA) models testing the effect of treatment with a regression that also included the Fall benchmark score as a covariate.

Table C.3. Effect of MRC on Student Literacy Outcomes by Grade

	Effect	Mean Difference	ANCOVA	
Grade	Hedges' $g$	Original Metric		
Kindergarten	0.52***	10.11***	10.08***	
First Grade	0.39***	6.85***	6.85***	
Second Grade	-0.03	-0.54	1.81	
Third Grade	-0.10	-2.09	0.96	

\*\*\*  $p < 0.001$

Table C.3 shows a substantial effect size for Kindergarten that is also highly significant; an average difference of approximately 10.1 letter sounds between program and control group students. A highly significant, substantial effect size was also found for first grade students; an average difference of 6.9 letters sounds within nonsense words between program and control group students. In the second and third grades, the evaluation team observed a slight negative mean difference, with an effect size that is less than meaningful ( $< 0.2$ ) and not statistically significant. Of note, when we control for the Fall test score, the direction of the effect is reversed, but remains statistically not significant.

## Appendix E: Glossary

**AIMLine:** A student's projected growth trajectory, measured from the most recent benchmark period to the next (e.g., Fall to Winter or Winter to Spring).

**AIMSWeb:** AIMSWeb is the web-based assessment tool used for progress monitoring and data management of all Minnesota Reading Corps K-3 students. The AIMSWeb assessments evaluate four critical literacy skills that are appropriate for specific K-3 grade levels and seasons: 1) letter naming fluency (Kindergarten), 2) letter sound fluency (First Grade – Fall/Winter), 3) nonsense word fluency (First Grade – Winter/Spring), and 4) oral reading fluency (Second and Third Grades).

**AmeriCorps:** AmeriCorps is a national service program run by the Corporation for National and Community Service that engages members to serve at nonprofit organizations, public agencies and faith-based organizations nationwide. In exchange for their service, AmeriCorps members receive a modest living stipend and Education Award. Minnesota Reading Corps is the nation's largest state AmeriCorps program.

**Benchmark:** A standard score above which students are considered "on-track" for grade level achievement. MRC lists grade and season (i.e., Fall, Winter, Spring) appropriate benchmark scores for each general outcome measure (i.e., AIMSWeb & IGIDI). Students' scores on benchmark assessments determine their eligibility for Minnesota Reading Corps services and serve as baseline data to determine students' improvements as a result of the program.

**"Big Five":** At the PreK level, the MRC program focuses on integrating the "Big Five" Early Literacy Predictors into all aspects of the daily classroom routine. The "Big Five" for preschool students include conversational skills, vocabulary and background knowledge, book and print rules, phonological awareness (i.e., rhyming and alliteration), and alphabetic knowledge.

**CNCS:** The Corporation for National and Community Service (CNCS) is a federal agency that engages more than 4 million Americans in service through Senior Corps, AmeriCorps, and the Social Innovation Fund, and leads President Obama's national call to service initiative, United We Serve. CNCS is funding the primary federal funder of the Minnesota Reading Corps program, and is funding the current evaluation of the MRC.

**Community Corps:** Community Corps members are embedded in preschool classrooms and collaborate with the classroom's lead teacher to help develop children's early literacy skills to prepare for Kindergarten. Community Corps members are responsible for enhancing the literacy-rich environment within the classroom, conducting Tier 2 and 3 interventions and conducting/ tracking progress monitoring for students.

**Community-based PreK:** Community-based PreK programs are run through community-based organizations such as community centers.

**DIBELS:** Dynamic Indicators of Basic Early Literacy Skills (DIBELS) are a set of assessments used for universal screening and progress monitoring in grades K-6. DIBELS assessments help educators identify students who may need additional literacy instruction in order to become proficient readers. In the MRC program it is used by some schools as alternative assessment to AIMSWeb.

**ELLCO:** The Early Language & Literacy Classroom Observation (ELLCO) tool is used to assess five key elements of a classroom's literacy environment: classroom structure, curriculum, language environment, books and book reading, print and early writing. According to the ELLCO, a "Literacy Rich Classroom" is one that embeds literacy activities among daily routines.

**Head Start:** Head Start is a federal PreK program designed to promote school readiness for low-income pre-Kindergarten students by enhancing their cognitive, social and emotional development. Through Head Start programs, enrolled children and families can also receive health, nutrition and other social support programs depending on eligibility.

**IGDI:** The Individual Growth and Development Indicators (IGDI) is a set of standardized, individually administered assessments that are used to evaluate children's language and emergent literacy skills. IGDI assess three key areas of emergent literacy: (1) Rhyming (Phonological Awareness); (2) Picture Naming (Vocabulary); and (3) Alliteration (Phonological Awareness).

**Internal Coach:** Individual trained by the Reading Corps to provide on-site literacy support and oversight to the MRC AmeriCorps member. Internal Coaches provide an on-site orientation for the MRC member, develop a daily schedule, assist in the implementation of literacy assessments, conduct integrity checks of the assessments and interventions, review student data and ensure the member is accurately reporting student data into AIMSWeb. The Internal Coach is a school employee, not a MRC member.

**K-3:** Kindergarten through third grade

**K-Focus:** A Kindergarten-Focused Literacy program in which members provide an additional 20 minutes of tutoring every day to small groups of students, typically focused on letter sound fluency. Kindergarten students who are served by K-Focus members receive a total of 40 minutes of tutoring every day.

**Literacy rich schedule:** Members in the PreK program work to implement and support a standard instructional regime/schedule that focuses on the "Big Five" emergent literacy skills (conversation skills, vocabulary and

background knowledge, book and print rules, phonological awareness-rhyming and alliteration, and alphabetic knowledge). Members assist the teaching team in implementing the literacy rich schedule and fostering a literacy rich classroom environment as defined by the Early Language and Literacy Classroom Observation (ELLCO), including name chart, theme-related books and props in five or more centers, sign-in area, writing center, word wall, etc.

**Master Coach:** Provides literacy coaching support to Internal Coaches and AmeriCorps members at multiple sites. The Master Coach schedules regular on-site visits to support and guide the site and its members in fulfilling the MRC program goals and ensures fidelity of implementation. The Master Coach provides training to members, conducts integrity checks, and reviews students' progress monitoring data. The Master Coach is an experienced literacy educator who serves as a consultant to MRC.

**Member:** A volunteer to who serves in the MRC AmeriCorps program. Member may refer to a volunteer in the K-3 program, or a PreK Professional Corps or Community Corps. Members deliver the one-on-one tutoring (PreK and K-3) and support implementation of the literacy rich schedule in MRC PreK classrooms. In recognition of their service, members receive a modest living stipend and Education Award.

**MDE:** Minnesota Department of Education.

**MRC:** The Minnesota Reading Corps (MRC) was started in 2003 to provide reading and literacy tutoring to children in PreK programs and students in Kindergarten through third-grade. The goal of the program is to ensure that students become successful readers and meet reading proficiency targets by the end of the third grade. MRC engages AmeriCorps members to provide literacy enrichment and tutoring services to PreK students. AmeriCorps members serve as one-on-one tutors and provide research-based interventions to both PreK and K-3 students who are just below proficiency in reading. As of the 2012-2013 school year, more than 1,100 AmeriCorps members implemented the program in 652 schools or sites and 184 school districts across the state of Minnesota.

**OnCorps:** A web-based database that stores information about students receiving MRC services. The database records student demographic information, assessment data, the amount of tutoring services students received, and other data such as: the number of books sent home, the number of times student's journals were completed, and family participation in MRC services

**PreK:** Preschool.

**Professional Corps:** Professional Corps members are current employees who are in a teaching position at the site. This member continues to fulfill their regular teaching responsibilities, but also incorporates specific MRC strategies in their instruction.

**Program Coordinator:** An employee of Minnesota Reading Corps, responsible for providing administrative oversight to the Minnesota Reading Corps program on a regional level, including member management, site management, and compliance with all AmeriCorps regulations. The Program Coordinator oversees regional recruitment efforts, works together with service sites in the interviewing, selection, and placement process for members.

**Progress monitoring:** A scientifically-based practice using weekly 1-minute reading tests to assess students' academic performance and evaluate the effectiveness of an intervention. Progress monitoring data helps teaching teams determine the effectiveness of interventions then make adjustments to instruction to ensure students reach their next benchmark target. For K-3, progress monitoring is conducted with all students receiving MRC tutoring each week by MRC members using 1-minute AIMSWeb tests. The scores are entered into AIMSWeb and used to create graphs that represent each student's progress relative to a specific intervention. For Pre-K, progress monitoring occurs monthly, for students receiving Tier 2 and 3 one-to-one intervention services.

**RtI:** Response to Intervention (RtI) is a practice of academic and behavior interventions designed to identify and provide early effective assistance to underperforming students. Research-based interventions are implemented and frequent progress monitoring is conducted to assess student response and progress. When students do not make progress, increasingly more intense interventions are introduced.

**SEEDS:** The SEEDS model is an interactive, skills-focused curriculum based on current research in early childhood education, child development, emergent literacy, and effective teaching. SEEDS is a relationship-based professional development program that provides a map to help adults *intentionally* demonstrate behaviors throughout their daily interactions with children that enrich academic growth and promote social/emotional well-being. SEEDS interaction include the following elements: **Sensitivity** – Look, listen, and ask questions to become aware of each child's needs, thoughts, abilities and feelings; **Encouragement** – Use intentional affirmations and positive non-verbal communication to create a shared positive learning environment; **Education** – Embed the "Big 5" literacy skills in daily routines (vocabulary, conversation, phonological awareness, book and print rules, and letter knowledge); **Development of Skills Through Doing** – Help children explore their world through hands-on learning; **Self-Image Support** – Balance the SEEDS quality interactions to support a child's feeling of being respected and capable.

**ServeMinnesota:** State Commission on AmeriCorps programs in Minnesota and responsible in Minnesota Law for Minnesota Reading Corps.

**Service hours:** The required hours of service AmeriCorps members must complete in order to fulfill their 11 months of service to AmeriCorps, and in return receive a living allowance and an education award to pay for college or pay back student loans. All full time members, K-3, Community Corps, and Professional Corps, must complete 1700 hours of service. Part time members must complete 920 hours. Service hours can be fulfilled not only through

members' time tutoring or working in the classroom, but also through participation in community and other school activities.

**Summer Institute:** A multi-day training program conducted over the summer to introduce new and old members, Internal Coaches, and Master Coaches to the Reading Corps program. The Institute consists of learning about the theories behind the program, the techniques used to implement the program, and the administrative components of the program. Education experts train Members and Coaches on all aspects of the program, and also provide time for practicing the techniques and the interventions. The Institute is also the time when most members will meet their Internal and Master Coaches for the first time.

**Tier 1-3:** Tier 1, 2, and 3 are the three "tiers" of a tiered instructional process lying at the core of the RtI model. Student scores on general outcome measure (e.g., AIMSWeb or IGDI) referenced to specific benchmarks determine a student's tier placement. The instruction that is then provided to students is based upon their respective tiers. Tier 1 students, approximately 75-80% of the population, are at the "Universal Level" and benefit from the standard whole class core literacy curriculum. They do not require supplemental instruction. Students who score in Tier 2 range, 15-20%, are those whose assessment scores are below the expected levels of achievement (benchmark) and are at risk for academic failure but are still above levels considered to indicate a high risk for failure. Tier 2 students typically are eligible for supplemental small group instruction. Students whose scores place them into Tier 3, approximately 5-10% of students, are considered to be at high risk for academic failure. They are typically offered one-to-one supplemental interventions and individualized educational plans.

**\*Tier 1 Instruction:** In PreK programs, this is instruction that students receive in the general education classroom. It includes Reading Corps directed intentional teaching with embedded and explicit instruction. In K-3 programs, this is considered the core literacy instruction provided in the classrooms for all students.

**\*Tier 2 Instruction:** (PreK program term) Provides additional, more intense instruction to children identified as needing extra help in targeted skill areas. Tier 2 instruction is in addition to Tier 1 instruction.

**\*Tier 3 Instruction:** (PreK program term) Provides the most intense intervention approach for children identified as needing extra help in a targeted skill area. Tier 3 instruction builds onto Tier 2 instruction by providing more individualized and intense instruction.
